

The grazing industry currently uses a large range of veterinary chemicals. Those applied to control livestock parasites are referred to as parasiticides. In the Queensland cattle industry, chemicals are used to control both internal parasites (e.g. gastrointestinal worms) and external parasites such as ticks, lice and buffalo fly. The degree of use depends mainly on the locality, cattle breed and the herd management system.

Parasiticides can be divided into three main groups, namely endectocides, ectocides and anthelmintics. Endectocides, such as ivermectin, doramectin and moxidectin are effective against a wide range of internal and external parasites. Ectocides are used against external parasites and anthelmintics against internal parasites.

Each parasiticide has one or more active constituents, which may be used by more than one company, resulting in up to several trade names for the same basic product. Trade names often give no indication as to the active constituent/s present. The active constituents are always listed on the container label beneath the trade name.

## Impact of Parasiticides on Dung Beetles

Reports of laboratory studies have led to a growing realization that the artive constituents of many parasitivides or their breakdown products may berm dung beetles.

Effects can range from the death of adult beetles, eggs or larvae to some form of impairment such as lowered breeding capacity of adults or retarded growth of Jarvae. The resultant impact on dung beetle populations is not known at present. Unfortunately there is also little or no available information about the toxicity of many chemicals for dung beetles.

Repeated use of some known higher risk products during the beetle-breeding season could reduce beetle populations on individual properties, with effects possibly extending to adjoining holdings. It is in the best interests of the cattle industry to encourage these beneficial insects, which, in returning dung to the sail, improve its aeration, increase nutrient recycling and assist in the control of cattle parasites that breed in dung.

The risk of harmful effects from chemical treatment coupled with a general lack of easily accessible information has created confusion amongst some producers who desire to treat parasites without harming their dung beetles.

The key to choosing appropriate parasiticides for your cattle is to:

- 1. Determine the parasite(s) that you want to treat
- 2. Identify the active constituents registered for their effective control
- 3. Be aware of the side effects these chemicals may have an dung beetles

Use this leaffet to help select an active constituent for your parasite problem that is low-risk for dung beetles. If circumstances require a higher risk chemical, try to reduce its impact by following the suggestions in this leaflet and in the Agforce Leaflet 'Strategic use of Parasiticides can help your Dung Beetles'.

Known effects of different types of active constituents on dung beetles are shown in *Italie I*. Note that, at most, only a few dung beetle species have been tested against some of the active constituents currently available. The possible impact of higher risk chemicals on dung beetle survival will vary depending on method and timing of application, frequency of treatment and the proportion of your total herd treated.

Table 1. Effects on dung beetles exposed to dung from cattle treated with various parasiticides as either pour-on, injectable or spray formulations.

REPORTED EFFECT ON DUNG BEETLES*					
	Mature adults	Young adults	Breeding females	Eggs/larvoe	
ENDECTOCIDES - Macrocyclic Lactones					
Avermectins: Abamectin, Doramectin, Eprinomectin, Ivermectin	No known Effect	Increased Mortality	Reduced Breeding	Increased Mortality	
Moxidectin**	No Known Effect				
ECTOCIDES · Synthetic Pyrethroids					
Cypermethrin	Increased Mortality	Increased Mortality	Reduced Breeding	Increased Mortality	
Deltamethrin	Increased Mortality	Increased Mortality	Reduced Breeding	Increased Mortality	
Flumethrin^	Not Tested				
ECTOCIDES - Organophosphate	s				
Chlorfenvinphos	Not Tested				
Diazinon	Not Tested				
ECTOCIDES - Growth Regulators					
Fluctures	Not Tested				
ECTOCIDES - Amines					
Amitraz	Not Tested				
ANTHELMINTICS					
Albendazole Fenbendazole Levamisole Mebendazole, Morantel Oxfendazole	No Known Effect				

<sup>\*</sup> This is a synthesis of information contained in CSIRO Contracted Report #56 by K. G. Wardhaugh (2000) and scientific papers or reports either mentioned therein or located independently. Effects noted have been reported at least once for one or more species.

The trade names under which commonly used active constituents are registered in the same formulations are shown in Table 2.

<sup>\*\*</sup> When used at recommended rates for cattle, has no known impact on Onthophagus gazella,

O. taurus, Euoniticellus intermedius and E. fulvus. Effects on other dung beetle species have not been fully evaluated.

<sup>^</sup> Refers to the spray formulation only; the pour-on is no longer available.

**Table 2.** Trade names and active constituents of endectocides and ectocides registered for cattle as pour-an, injectable or spray formulations.

ENDECTOCIDES - Macrocyclic Lactones			
Abamectin	Avormec Antiparasitic Injection, Cattlegard Injectable, Duotin Antiparasitic Injection, Genesis Antiparasitic Cattle Injection, Genesis Pour-On, Paramectin Injection, Raramectin Pour-On, Paramectin RV Pour-On, Rycomectin Antiparasitic Cattle Injection, Virbac Virbamec Antiparasitic Injection, Virbamec Pour-On, Virbamec Pour-On, Virbamec Pour-On, Virbamec Pour-On, WSD Abamectin Pour-On Antiparasitic, WSD Abamectin Pour-On Endectocide		
Doramectin	Dectomax Injectable Endectocide, Dectomax Pour-On Endectocide		
Eprinomectin	Ivamec Eprinex Pour-On for Beef & Dairy Cattle		
lvermectin	Baymec Rour-On, Bornectin Antiparasitic Injection, Cevamec Injection, Coopers Paramax Pour-On, Ecomectin Injection, Ecomectin Cattle Rour-On, Genesis Injection, Genesis Ultra Injection, Genesis Ivermectin Pour-on, Ivermectin Baymec Pour-on, Ivormec Antiparasitic Injection, Nomec Plus Broad Spectrum Antiparasitic Injection, Normec Pour-On, Virbac Virbamax Plus Antiparasitic Injection, Normectin Injectable, Normectin Pour-On, Virbac Dairymec Pour-On, Virbac Beefmec Pour-On, Virbac Antiparasitic Injection, Virbac Virbamax Pour-On, Virbac Virbamec IV Rour-on, Virbac Virbamec IV Rour-on, Virbac Virbamec IV Rour-on, Virbac Virbamec IV Rour-On		
Moxidectin	Cydectin Injection, Cydectin Pour-On		
ECTOCIDES - Synthetic Pyrethroids			
Deltamethrin	Arrest Easy-Dose Pour-On, Arrest Pour-On, Bombard Pour-On, Coopers Easy- Dose Pour-On, Coopers Coopafly Pour-On, Todel Pour-On, Virbac Deltamethrin Pour-On		
Cypermethrin	Cypafly Buffalo Fly Spray		
Flumethrin	Bayticol Cattle Dip & Spray		
ECTOCIDES - Organophosphates			
Chlorfenvinphos	Supona Buffalo Fly Insecticide		
Diazinon	Nucidol 200 Insecticide & Acaricide, WSD Diazinon for Sheep, Cattle, Goats		
ECTOCIDES - SP/OP Combinations			
Cypermethrin + Chlorfenvinphos	Barricade 'S' Cattle Dip & Spray, Coopers Blockade 'S' Cattle Dip & Spray		
Deltamethrin + Ethion	Arrest Fly & Tick Dip & Spray for Cattle, Coopers Tixafly Cattle Dip & Spray		
ECTOCIDES - Growth Regulators			
Fluazuron	Acatak Pour-On Tick Development Inhibitor		
ECTOCIDES - Amines			
Amitroz	Amitraz EC Cattle & Pig Spray, Coopers Amitik EC Cattle & Pig Spray, Coopers Amitik Cattle Dip & Spray, Taktic WP Cattle Dip & Spray, Taktic EC Acaricidal Spray for Cattle & Pigs, Tickoff WP Cattle Tickicide		

# Usage, excretion routes and toxic effects of Parasiticides

#### Macrocyclic Lactones (MLs)

- MLs have the broadest spectrum of activity of all. Avermectins have been used in beef cattle for years against worms and cattle tick, with a bonus of buffalo fly and louse control. Maxidectin is used to treat worms and cattle tick.
- Eprinomectin and moxidectin are now registered for use on dairy cattle.
- Macrocyclic lactones are excreted in the dung of treated animals.
- Avermentins exert their most harmful effects in dung for a period of 2 to 3 weeks after treatment.
- If used in accordance with the manufacturer's instructions for the treatment of cattle, maxidetis is not known to be harmful to dung beetles.
- Same dung beetle species are more susceptible to evermentis than others.

### Synthetic Pyrethroids (SPs)

- Once used extensively for cattle tick control, these are now employed mainly against buffalo fly. The fly has developed a high level of resistance to most SPs in some areas.
- Probably all synthetic pyrethroids are excreted in the dung of treated animals, but their toxicities for dung beetles vary. Most 59s tested showed some insecticidal effects.
- Same SPs can cause high mortality in adult beetles for up to a week or wore after treatment and thus have considerable potential to affect beetle populations.
- Some dung beetle species are more susceptible to SPs than others.

### Organaphosphates (OPs)

- OPs can provide effective and economical control of ticks, buffalo flies and lice.
- Two OPs (chlorfenvinphas & diazinan) are also registered for use in both backrubbers and ear tags.
- There are reports of low-level resistance to both chlorfenvinphos and diazinon in buffalo fly.
- A useful strategy for buffalo fly control in southeast Queensland is to fit OP ear tags to cattle in January, which provide control until the

- and of the fly season. OP sprays can be used earlier in the season if control is necessary.
- No information is available about possible toxic effects of OPs for dung beetles – thiories in the and diszines are mainly excreted in the urise and thus unlikely to be harmful.

### Growth Regulators & Amines

- · Used for the control of ticks.
- Inadequate information is currently available about excretion rautes of fluctures and amitraz and their effects on duna beetles.

#### Anthelmintics

- Used for control of gastrointestinal worms and flukes.
- Generally not harmful to beetles. Main excretion route of the drugs or their residues can be via either urine or dung.

#### Other Chemicals

SP/OP combinations

- These blends were developed largely to control the widespread DDT-resistant cattle ticks exhibiting a low level of cross- resistance to the SPs. These are:
  - cypermethrin plus chlorlenvinphos (in Barricade 'S', Blockade 'S'); and
  - deltamethrin plus ethian (in Tixaffy and Arrest Dips & Sprays for Cattle)
- These are commonly used but, because they contain much less SP than products containing the same SPs alone, they may be less harmful to dung beetles than the latter.

1. Can you change to less toxic chemicals?

Avaid using averanectins and all SP pour-ons or backliners whenever possible during the beetle breeding season. For buffalo fly control alone, consider changing the application method (see 5 below).

Timing of treatment is critical.

If possible, don't use potentially harmful chemicals during the season when most dung beetles are active (October to March in most areas), extending to June in southeast Queensland to cater for the future spread of the autumn-active species *Onitis caffer*.

3. Reduce the frequency of treatment.

Ensure the decision to treat with a parasiticide focuses on production and economic benefits. Is it really necessary?

- 4. Target freatment to specific animals or groups of animals.
  Does your whole herd need treatment e.g. do you only need to treat the weaners for worms, or perhaps the bulls for flies?
- The method of application.

Injectables, pour ans and plunge dips are thought to deliver the most chemical to the tissues of treated animals. Residues of MLs and SPs are then excreted in the dung. For buffalo fly control, remember that oversprays, backrubbers, dust bags and ear tags result in less chemical contamination of the dung.

Use recommended dose rates.

Where research has shown a chemical to be safe for dung beetles, this is based on its use at the recommended dose rate.
